

# Carbon Footprint Reporting

To estimate my carbon footprint, I decided to use the WWF calculator and the Finnish Environmental Institution tool. I obtained the following results:

First, we can observe that the percentage differ greatly between the two tools. The WWF calculator estimates my food consumption as 50% of my footprint, whereas the Finnish Institute estimates my housing as my main carbon contribution. Since the second tool was more precise about housing information, I can consider their estimations as the best ones.

The Finnish tool also permits to compare your value to different other average. I chose to compare with the average having the same type of housing. I can see that my housing is far below the average. I think it is mainly because I don't know much about the information asked, and my real consumption must be somewhat near the average.

In term of mobility, I only walk or use the bus, so my footprint is not high.

In conclusion, since I try to reduce as much as I can my consumption to reduce my footprint, my real values must be somewhat below the average for Finland, but far below for France (or England as WWF estimates). I can also tries to minimize more my food waste.
